RFID tags are subject to viruses

By Jeremy Kirk, IDG news service

Three computer science researchers are warning that viruses embedded in radio tags used to identify and track goods are right around the corner, a danger so far overlooked by the industry's high interest in the technology.

No RFID viruses have been released live as of now, according to the researchers at Vrije Universiteit in Amsterdam. But RFID tags have several characteristics that could be engineered to exploit vulnerabilities in middleware and back-end databases, they wrote in a paper presented at a conference in Pisa, Italy

"RFID malware is a Pandora's box that has been gathering dust in the corner of our 'smart' warehouses and home," the paper stated.

The attacks can come in the form of a SQL injection or a buffer overflow attack even though the tags themselves may only store a small bit of information, the paper said. For demonstration purposes, the researchers created a proof-of-concept, self-replicating RFID virus.

It only took a master's student at the university, Patrick Simpson, four hours to write a virus small enough to fit on a RFID tag, something previously thought unworkable, said Andrew S. Tanenbaum, a professor at Vrije Universiteit Amsterdam. RFID tags can contain as little as 114 bytes of memory, he said.

Tanenbaum expects vendors to be angry about the publishing of the code. Vendors have dismissed the possibility of RFID viruses, saying that the amount of memory in the tags is too small, he said.

"You publish all of the code on the website, and all of [a] sudden, [vendors] are going to start panicking," Tanenbaum said. "This hopefully will make them take it seriously. This is a wake-up shot before this stuff is deployed in a large scale."

The purpose of the exercise, the authors wrote, is to encourage RFID middleware designers to be more careful when writing code. Back-end middleware can contain millions of lines of source code, and if

software faults number between six to 16 per 1,000 lines of code, the programs are like to have many vulnerabilities, the paper said.

RFID tags are increasingly being used in a variety of industries to track items and give a real-time view of inventories. The tags contain data on a particular object or, in some cases, embedded in animals, and that data is typically stored in a database.

Companies can save money by using the tags to keep closer tabs on their property. However, this "pervasive computing utopia has its dark side," the authors wrote.

RFID systems may be attractive to criminals since the data contained on them may have a financial or personal nature, such as information stored on digital passports. In addition to causing damage to computer systems, RFID malware may have an effect on real-world objects, the paper said.

Airports are looking to RFID tags to better track baggage. But Tanenbaum warned that this application could pose a large problem if an RFID tag is read and delivers a much larger set of data in return.

A false tag on a piece of baggage could exploit a buffer overflow, delivering a virus to the RFID middleware, according to Tanenbaum. Once the virus code is on the server, it can infect the databases and corrupt subsequent tags or install "backdoors" - small programs that allow for the extrication of data over the Internet, he said.

"You can hide baggage," Tanenbaum said. "You can reroute baggage to the wrong place - all kinds of mischief. That's I think a very, very serious thing that even has national security implications."
